# Radon-Nikodým derivatives and disintegration for s-finite measures:

some semantic bases for probabilistic metaprogramming

Luke Ong Matthijs Vákár

University of Oxford

# Seminar 113: Metaprogramming for Statistical Machine Learning 21-25 May 2018, Shonan Village Centre

# Outline

- Introduction: s-finite-measure semantics of an idealised 1st-order probabilistic programming language
- 2 Properties of s-finite measures and kernels
- 3 Radon-Nikodým derivatives
- 4 Conditional distribution and disintegration
- 5 Conclusions and further directions

# A typed 1st-order probabilistic programming language, PPL

Idealised, 1st-order version of Church, Anglican, Venture, Hakura, etc. (Staton et al. LICS 2016)

**PPL Types.**  $A, B ::= \mathbb{R} | P(A) | 1 | A \times B | \sum_{i \in I} A_i$ , where I is countable, nonempty.

- Types A are interpreted as measurable spaces [[A]].
- $[\mathbb{R}]$  is the measurable space of reals with its Borel sets.
- $[\![P(A)]\!]$  is the measurable space of probabilistic measures on  $[\![A]\!]$  (i.e. "Giry monad").
- The type of booleans and natural numbers are definable.

## PPL Terms-in-context. Two typing judgements:

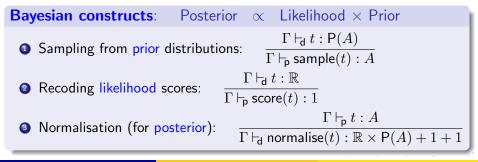

- $\Gamma \vdash_{\mathsf{d}} t : A$  for deterministic terms
- $\Gamma \vdash_{\mathbf{p}} t : A$  for probabilistic terms

**Sums and products**. The language includes variables, and standard constructors and destructors for sum and product types.

Sequencing: monadic unit, and bind

$$\frac{\Gamma \vdash_{\mathsf{d}} t : A}{\Gamma \vdash_{\mathsf{p}} \mathsf{return}\,(t) : A} \qquad \qquad \frac{\Gamma \vdash_{\mathsf{p}} t : A \qquad \Gamma, x : A \vdash_{\mathsf{p}} u : B}{\Gamma \vdash_{\mathsf{p}} \mathsf{let}\, x = t \,\mathsf{in}\, u : B}$$

Language-specific constructs. Constants for all measurable functions.

## Semantics of PPL (Staton, ESOP 2017)

- Interpret  $\Gamma \vdash_{\mathsf{d}} t : A$  as a measurable function  $\llbracket t \rrbracket : \llbracket \Gamma \rrbracket \to \llbracket A \rrbracket$
- Interpret  $\Gamma \vdash_{\mathbf{p}} t : A$  as an s-finite kernel  $\llbracket t \rrbracket : \llbracket \Gamma \rrbracket \rightsquigarrow \llbracket A \rrbracket$ .

DEF. A kernel k from  $(X, \Sigma_X)$  to  $(Y, \Sigma_Y)$  is function  $k : X \times \Sigma_Y \to [0, \infty]$  s.t. i.  $\forall x \in X, \ k(x, -) : \Sigma_Y \to [0, \infty]$  is a measure ii.  $\forall U \in \Sigma_Y, \ k(-, U) : X \to [0, \infty]$  is a measurable function. (Henceforth identify measures with kernels  $\mu : 1 \times \Sigma_Y \to [0, \infty]$ )

Kernel $k(-,-)$	Definition
subprobability	$\sup_{x \in X} k(x, Y) \le 1$
finite	$\sup_{x \in X} k(x, Y) < \infty$
$\sigma$ -finite	$\exists (Y_i \in \Sigma_Y)_{i \in \omega} (Y = \biguplus_i Y_i \& \forall i . \sup_{x \in X} k(x, Y_i) < \infty)$
s-finite	$k = \sum_{i \in \omega} k_i$ , each $k_i$ is a finite kernel $X \rightsquigarrow Y$ .

The classes above form an increasing chain (ordered by  $\subseteq$ ).

# Examples of $\sigma$ -finite / s-finite measures

DEF. Let  $(X, \Sigma_X)$  be a measurable space;  $\mu : \Sigma_X \to [0, \infty]$  be a measure. •  $\mu$  is  $\sigma$ -finite if  $X = \biguplus_{i \in \omega} X_i$  with each  $X_i \in \Sigma_X$  and  $\mu(X_i) < \infty$ . •  $\mu$  is s-finite if  $\mu = \sum_{i \in \omega} \mu_i$ , and each  $\mu_i(X) < \infty$ .

**Intuition**: "bad  $\infty$ " is  $\infty$  concentrated at a point.

- $\sigma$ -finiteness only admits "good  $\infty$ "
- ullet s-finiteness can admit "bad  $\infty$ ", but only countably many.

#### Examples

- **1** The Lebesgue measure, Leb, is  $\sigma$ -finite.
- 2 The  $\infty$ -measure on the point 1 is s-finite, but not  $\sigma$ -finite;
- **③** Counting measure  $\#_S$  on any uncountable standard Borel space S is not s-finite
- $\infty \cdot Leb$  is not s-finite. (Convention:  $0 \cdot \infty = 0$ .)

白 医水疱 医水黄 医水黄素 医

# s-finite-measure semantics of PPL (Staton, ESOP 2017)

Context 
$$\Gamma = (x_1 : A_1, \cdots, x_n : A_n)$$
, with  $\llbracket \Gamma \rrbracket := \prod_{i=1}^n \llbracket A_i \rrbracket$ .

## Semantics of PPL

- Interpret  $\Gamma \vdash_{\mathsf{d}} t : A$  as a measurable function  $\llbracket t \rrbracket : \llbracket \Gamma \rrbracket \to \llbracket A \rrbracket$
- Interpret  $\Gamma \vdash_{\mathbf{p}} t : A$  as an s-finite kernel  $\llbracket t \rrbracket : \llbracket \Gamma \rrbracket \rightsquigarrow \llbracket A \rrbracket$ .

# Theorem (Definability) If kernel $k : \llbracket \Gamma \rrbracket \rightsquigarrow \llbracket A \rrbracket$ is s-finite, then there is a term $\Gamma \vdash_{p} t : A$ s.t. $k = \llbracket t \rrbracket$ .

This is a very useful result (for us)!

- 本間下 本臣下 本臣下 三臣

Infinite measures seem unavoidable.

- No known useful syntactic restriction that enforces finite measures.
- A program with finite measure may have subexpression with infinite measure.

 $\sigma$ -finite measures are a much-studied class of infinite measures, but they are not suitable for interpreting probabilistic programming languages.

- The pushforward of a s-finite measure is s-finite; but the pushforward of a  $\sigma$ -finite measure is generally only s-finite.
- Failure of kernel composition of  $\sigma$ -finite measures: let  $U \in \Sigma_1$

$$[\vdash_{\mathsf{p}} \mathsf{let}\, x = Leb \,\mathsf{in}\,\mathsf{return}\,\,():1]](U) = \int_{\mathbb{R}} Leb(\mathrm{d}z)\,\chi_{()}(U) = \infty \cdot \chi_{()}(U).$$

Leb (Lebesgue measure) is  $\sigma$ -finite, however the composite is s-finite, and not  $\sigma$ -finite

- 5 Conclusions and further directions

# Outline

Introduction: s-finite-measure semantics of an idealised 1st-order probabilistic programming language

## 2 Properties of s-finite measures and kernels

3 Radon-Nikodým derivatives

4 Conditional distribution and disintegration

5 Conclusions and further directions

## **Product measures**

Given measure  $\mu$  on X and kernel  $\nu$  from X to Y, call measure  $\Psi$  on  $X \times Y$  a product measure of  $\mu$  and  $\nu$  if  $\Psi(U \times V) = \int_U \mu(\mathrm{d}x) \nu(x, V)$ , for all  $U \times V \in \Sigma_{X \times Y}$ .

- By Carathéodory Extension Theorem, a maximal product measure  $\mu\otimes\nu$  always exists:

$$(\mu \otimes \nu)(W) := \inf \left\{ \sum_{i \in \omega} \int_{U_i} \mu(\mathrm{d}x) \nu(x, V_i) \mid W \subseteq \bigcup_{i \in \omega} (U_i \times V_i) \in \Sigma_{X \times Y} \right\}$$

- Product measures may be defined via iterated integration:

$$(\mu \otimes^l \nu)(W) := \int_X \mu(\mathrm{d}x) \int_Y \nu(x, \mathrm{d}y) \ \chi_W(x, y)$$

and, in case  $\nu(x)$  is independent of x, i.e.,  $\nu$  is a measure on Y

$$(\mu \otimes^r \nu)(W) := \int_Y \nu(\mathrm{d}y) \int_X \mu(\mathrm{d}x) \ \chi_W(x,y).$$

# Fubini theorem—for swapping order of integration

Even when  $\otimes^l$  and  $\otimes^r$  are well-defined, they may not be equal: - For non-*Leb*-null  $V \in \Sigma_{\mathbb{R}}$ :

$$\otimes^{l}: \quad \int \#_{\mathbb{R}}(\mathrm{d}x) \Big( \int Leb(\mathrm{d}y) \left\{ (r,r) \mid r \in V \right\} \Big) = 0$$
$$\otimes^{r}: \quad \int Leb(\mathrm{d}y) \Big( \int \#_{\mathbb{R}}(\mathrm{d}x) \left\{ (r,r) \mid r \in V \right\} \Big) = Leb(V).$$

## Theorem (Fubini)

For an s-finite measure  $\mu$  on X, and an s-finite kernel  $\nu$  from X to Y

- i.  $\mu \otimes^{l} \nu$  is well-defined, and  $\mu \otimes \nu = \mu \otimes^{l} \nu$ .
- ii. Further, if  $\nu$  is simply a measure on Y,  $\mu \otimes^r \nu$  is also well-defined, and  $\mu \otimes \nu = \mu \otimes^l \nu = \mu \otimes^r \nu$ .

## s-finite kernels: T.F.A.E.

- $\textcircled{0} \ \nu \text{ is a s-finite kernel from } X \text{ to } Y$
- 2  $\nu = \sum_{n \in \omega} \nu_n$  for subprobability kernels  $\nu_n$ .
- **③**  $\nu$  is the pushforward of a  $\sigma$ -finite kernel.

Given kernel  $k: X \rightsquigarrow Y$  and measurable function  $f: Y \to Z$ , define the pushforward kernel  $f_*k: X \rightsquigarrow Z$  by: for  $x \in X$ ,  $U \in \Sigma_Z$ ,  $f_*k(x, U) := k(x, f^{-1}(U))$ .

## s-finite measures

•  $\nu$  is a s-finite measure iff there is a  $\sigma$ -finite measure  $\mu$  on X and a measurable function  $f: X \to \{1, \infty\}$  such that  $\nu = \mu(f)$ .

A weak converse: if *ν* is an s-finite measure on *X*, then either *ν* is zero or *ν* = P(*f*) for a probability measure P and a measurable function *f* : *X* → [0, ∞] with P([*f* = 0]) = 0.

## s-finite measures and $\infty$ -sets

Fix a measure  $\mu$  on a measurable space  $(X, \Sigma_X)$ .

DEF.  $U \in \Sigma_X$  is an  $\infty$ -set w.r.t.  $\mu$  if (i)  $\mu(U) = \infty$ , and (ii) for all  $V \in \Sigma_U$ ,  $\mu(V) = 0$  or  $\infty$ .

- If  $\mu$  is  $\sigma$ -finite then it does not have any  $\infty$ -sets (:: any set U of infinite  $\mu$ -measure must have a countable partition of finite  $\mu$ -measure, i.e., 0). - IDEA: presence of  $\infty$ -sets distinguishes s-finite from  $\sigma$ -finite measures.

Call  $U \in \Sigma_X$  a  $\sigma$ -finite complement of X if (i) U is an  $\infty$ -set or a null-set, and (ii)  $\mu$  is  $\sigma$ -finite on  $X \setminus U$ .

Theorem. Let  $\mu$  be an s-finite measure on X. Then

- i. There exists a  $\sigma$ -finite complement in  $\Sigma_X$ .
- ii.  $\mu$  is  $\sigma$ -finite iff there are no  $\mu$ - $\infty$ -sets in  $\Sigma_X$ .

The converse of (i) fails: not every measure  $\mu$  which has a  $\sigma$ -finite complement need be s-finite. Take  $\mu = \#_{\mathbb{R}} \cdot \infty$ .

Ong & Vákár (University of Oxford) R-N derivatives, disintegration & s-finiteness

# Outline

- Introduction: s-finite-measure semantics of an idealised 1st-order probabilistic programming language
- Properties of s-finite measures and kernels
- 3 Radon-Nikodým derivatives
  - 4 Conditional distribution and disintegration
  - 5 Conclusions and further directions

Let  $\mu$  and  $\nu$  be measures on X. A Radon-Nikodým derivative of  $\mu$  w.r.t.  $\nu$  is a measurable function  $X \to [0, \infty]$ , typically written  $d\mu/d\nu$ , s.t.

$$\mu = \nu \left(\frac{\mathrm{d}\mu}{\mathrm{d}\nu}\right) := \int_X \nu(\mathrm{d}x) \frac{\mathrm{d}\mu}{\mathrm{d}\nu}(x). \qquad \text{Notation. } \nu(f) = \int_X \nu(\mathrm{d}x) f(x).$$

Recall:  $\mu$  is absolutely continuous w.r.t.  $\nu$  (written  $\mu \ll \nu$ ) if  $\forall U \in \Sigma_X . \nu(U) = 0 \implies \mu(U) = 0.$ 

### Theorem (Radon-Nikodým – standard version)

Let  $\mu \ll \nu$  be  $\sigma$ -finite measures on a space  $(X, \Sigma_X)$ . Then  $\mu$  has a R-N derivative w.r.t.  $\nu$ , which is unique up to  $\nu$ -equivalence.

The pdf of a r.v. is the R-N derivative of the induced measure with respect to some stock measure (usually the Lebesgue measure for continuous r.v.).

- Provides existence proof of conditional expectation for probability measures key concept in probability theory.
- Basis of compilation of prob. programs to densities (Bhat et al. POPL12; LMCS17; etc.)

#### Let $\mu, \nu$ be s-finite measures on $(X, \Sigma_X)$ .

DEF.  $\mu$  is  $\infty$ -absolutely continuous w.r.t.  $\nu$  (written  $\mu \ll \nu$ ) if (i)  $\mu \ll \nu$ , and (ii) for all  $\nu$ - $\infty$ -sets U, U is a  $\mu$ - $\infty$ -set or a  $\mu$ -null-set.

- For  $\sigma$ -finite measure  $\nu$ , we have  $\mu \overset{\infty}{\ll} \nu$  iff  $\mu \ll \nu$ , vacuously.
- If  $\mu$  has density f w.r.t.  $\nu$  (i.e.  $\mu = \nu(f)$ ) then  $\mu \stackrel{\infty}{\ll} \nu$ .

DEF. Let  $f, g: X \to [0, \infty]$  be measurable, and let  $X_{\infty} \in \Sigma_X$  be a  $\sigma$ -finite complement w.r.t.  $\nu$ . Say f and g are  $\nu$ - $\infty$ -equivalent if  $\nu([f \neq g] \cap (X \setminus X_{\infty})) + \nu([g = 0 \neq f] \cap X_{\infty}) + \nu([f = 0 \neq g] \cap X_{\infty}) = 0$ 

- On the  $\sigma\text{-finite}$  part of X:~f and g are  $\nu\text{-equivalent}$ 

- On  $\sigma$ -finite complement of X: the points where one has value 0 and the other strictly positive are  $\nu$ -negligible.

## Theorem (Radon-Nikodým for s-finite measures)

Let  $\mu \stackrel{\infty}{\ll} \nu$  be s-finite measures on a space  $(X, \Sigma_X)$ . Then  $\mu$  has a R-N derivative w.r.t.  $\nu$ , which is unique up to  $\nu$ - $\infty$ -equivalence. [False if only assume  $\mu \ll \nu$ .]

# Application

Let  $\mu \ll \nu$  be s-finite measures on X. Then there exists an RN-derivative  $d\mu/d\nu : X \to [0,\infty]$ , satisfying  $\nu(d\mu/d\nu) = \mu$ , unique up to  $\nu$ - $\infty$ -equivalence.

#### **1** Importance sampling of $\mu$ w.r.t. $\nu$ .

sample 
$$\mu = \text{let} (\text{sample } \nu)$$
 be  $x$  in  $\left(\text{score}\left(\frac{\mathrm{d}\mu}{\mathrm{d}\nu}(x)\right); \text{return } x\right)$ .

**2** Rejection sampling of  $\mu$  w.r.t.  $\nu$ . Assume  $d\mu/d\nu \leq M \in [0, \infty)$ . Let

$$\begin{split} f(z) &:= \mathsf{let}\;(\mathsf{sample}\;\nu)\;\mathsf{be}\;x\;\mathsf{in}\\ &(\mathsf{sample}\;\mathbb{U}_{[0,1]})\;\mathsf{be}\;y\;\mathsf{in}\\ & \mathsf{if}\;\Big(y \leq \frac{1}{M}\frac{\mathrm{d}\mu}{\mathrm{d}\nu}(x)\Big)\;\mathsf{then}\;(\mathsf{return}\,x)\;\mathsf{else}\;z. \end{split}$$

Then, we get a rejection sampling procedure for  $\mu$ : sample  $\mu = \mathbf{Y}(f)$ .

# Outline

- Introduction: s-finite-measure semantics of an idealised 1st-order probabilistic programming language
- 2 Properties of s-finite measures and kernels
- 3 Radon-Nikodým derivatives
- 4 Conditional distribution and disintegration

## Conclusions and further directions

## Disintegration

- Disintegration formalises the idea of a non-trivial "restriction" of a measure to a measure-zero subset of the measure space in question.
- It is closely related to the existence of conditional probability measures.
- Disintegration may be viewed as a process opposite to the construction of a product measure.

And hence it is related to Fubini theorem.

Let x be a point on Earth's surface drawn from a uniform distribution. If x lies on the equator, its longitude should be uniformly distributed over  $[-\pi, \pi]$ .

But there is nothing special about the equator: it's just a great circle. In particular, for a great circle through the poles (i.e. conditioning on the longitude) there should be conditional probability 1/4 that x lies north of latitude  $45^{\circ}N$ .

Now "average out" over the longitude to deduce that x has probability 1/4 of lying in the spherical cap extending from the north pole down to the  $45^{\circ}$  parallel of latitude.

Alas, that cap does not cover 1/4 of the Earth's surface area, as would be required for a point uniformly distributed over Earth's surface.

(Pollard 2002)

Kolmogorov (1930): "The concept of a conditional probability with regard to an isolated hypothesis whose probability equals 0 is inadmissible."

## **Review: Conditioning for discrete random variables**

Straightforward – provided we eschew conditioning on probability-0 events.

DEF. Conditional probability. Assume  $\mathbb{P}$  is a probability measure on  $(X, \Sigma_X)$ . Suppose r.v. T takes value in  $R \subseteq_{\text{fin}} Y$ . For  $A \in \Sigma_X, y \in R$ 

$$\mathbb{P}(A \mid T = y) := \frac{\mathbb{P}(A \cap \{T = y\})}{\mathbb{P}(\{T = y\})}$$

**Properties:** Writing  $\mathbb{P}_y(-)$  for the measure  $\mathbb{P}(- \mid T = y)$ 

- i. Pre-regularity.  $\mathbb{P}_y$  is a probability measure on X, for all  $y \in R$ .
- ii. Concentration.  $\mathbb{P}_y$  concentrates on  $\{T = y\}$ :

$$\mathbb{P}_{y}(\{T \neq y\}) = \frac{\mathbb{P}(\{T \neq y\} \cap \{T = y\})}{\mathbb{P}(\{T = y\})} = 0.$$

iii. Weighted average. For all  $A \in \Sigma_X$ ,  $\mathbb{P}(A) = \sum_{y \in R} \mathbb{P}(\{T = y\}) \mathbb{P}_y(A)$ 

Question: How to extend conditional probability  $\mathbb{P}(A \mid T = y)$  to general spaces  $(X, \Sigma_X)$  and arbitrary measurable T?

## Fundamental Theorem & Definition (Kolmogorov, 1933)

Given triple  $(\Omega, \mathcal{F}, \mathbb{P})$ , r.v. X with  $E(|X|) < \infty$ , and  $\mathcal{G}$  a sub- $\sigma$ -algebra of  $\mathcal{F}$ . There exists r.v. Y s.t. (i) Y is  $\mathcal{G}$  measurable, (ii)  $E(|Y|) < \infty$ , and (iii)  $\forall G \in \mathcal{G}$ .  $\int_{G} \mathbb{P}(\mathrm{d}\omega) Y(\omega) = \int_{G} \mathbb{P}(\mathrm{d}\omega) X(\omega)$ . Moreoever, if Y' is another r.v. satisfying the above, then Y = Y' a.s., and is called a version of conditional expectation  $E(X \mid \mathcal{G})$  of X given  $\mathcal{G}$ .

- There is a gap between intuition and rigour in conditioning arguments.

- An accounting problem: for  $F \in \mathcal{F}$  define  $\mathbb{P}(F \mid \mathcal{G})$  to be  $E(\chi_F \mid \mathcal{G})$ . For a fixed seq.  $(F_n)$  of disjoint elts of  $\mathcal{F}$ ,  $\mathbb{P}(\bigcup F_n \mid \mathcal{G}) = \sum \mathbb{P}(F_n \mid \mathcal{G})$  a.s. In general, there are uncountably many such sequences; we cannot conclude (:: uncountably many null-sets) that there is a kernel  $P: \Omega \times \mathcal{F} \to [0, 1)$  s.t. (a)  $\forall F \in \mathcal{F}, P(-, F)$  is (version of)  $\mathbb{P}(F \mid \mathcal{G})$ , (b) for almost every w,  $\mathbb{P}(w, -)$  is a probability measure on  $\mathcal{F}$ .

## Definition: disintegration of a measure

Let  $T:X\to Y$  be measurable;  $\mu$  and  $\nu$  be measures on X and Y resp.

DEF. A  $(T, \nu)$ -disintegration (or -conditional distribution) of  $\mu$  are a family  $\{\mu_y\}_{y \in Y}$  of measures on X and a  $\nu$ -null set  $N \in \Sigma_Y$  s.t.

- i. Regularity:  $(y, U) \mapsto \mu_y(U)$  is a kernel from Y to X;
- ii. Concentration:  $\forall y \in Y \setminus N$ ,  $\mu_y$  concentrates on  $\{T = y\}$ , i.e.,  $\mu_y$  is supported in  $T^{-1}(y)$ :  $\forall V \in \Sigma_X$ ,  $\mu_y(V) = \mu_y(V \cap T^{-1}(y))$ ;
- iii. Weighted average:  $\forall V \in \Sigma_X$ ,  $\mu(V) = \int_Y \nu(\mathrm{d}y) \ \mu_y(V)$ .

Often write  $\mu(- | T = y)$  for  $\mu_y$ . iii'. For all measurable  $f : X \to [0, \infty]$ ,

$$\int_X \mu(\mathrm{d} x) \ f(x) = \int_Y \nu(\mathrm{d} y) \ \int_{T^{-1}(y)} \mu_y(\mathrm{d} x) \ f(x).$$

Shonan Seminar 113

24 / 30

The standard Disintegration Theorem for  $\sigma$ -finite measures satisfies a weaker definition: if CH holds,  $\mu_{-}(-)$  cannot be a kernel (Maharam's 1950 Problem: Back et al. 2015).

Ong & Vákár (University of Oxford) R-N derivatives, disintegration & s-finiteness

# A disintegration theorem for s-finite measures

Let  $T:X\to Y$  be measurable from a standard Borel space X to a measurable space Y, let  $\mu$  and  $\nu$  resp. be measures on X and Y.

Existence

Assume (i)  $\mu, \nu$  s-finite, (ii)  $T_*\mu \ll \nu$ , and (iii) for all  $\nu$ -∞-sets U,  $T^{-1}(U)$  is a  $\mu$ -∞-set or a  $\mu$ -null-set<sup>a</sup>. Then there exists a  $(T, \nu)$ -disintegration of  $\mu$ ,  $\{\mu_y\}_{y\in Y}$ , which is an s-finite kernel.

N.B. Theorem fails for s-finite  $\mu, \nu$  if we only demand  $T_*\mu \overset{\infty}{\ll} \nu$ .

<sup>a</sup>(ii) and (iii) are strictly stronger than  $T_*\mu \stackrel{\infty}{\ll} \nu$ .

#### Uniqueness

If  $\nu$  is s-finite, then the  $(T, \nu)$ -disintegration of  $\mu$  (qua s-finite kernel) is unique up to  $\nu$ - $\infty$ -equivalence.

・ロト ・ 母 ト ・ ヨ ト ・ ヨ ト ・ ヨ

## Fubini's theorem for s-finite measures

Let  $\mu = \alpha \otimes \beta$  be a product of s-finite measures on product space  $X \times Y$ . Let  $T : X \times Y \to Y$  be  $(x, y) \mapsto y$ .

Then the  $(T,\beta)$ -disintegration of  $\mu$  is  $\{\mu_y\}_{y\in Y}$ , where  $\mu_y = (R_y)_*(\alpha)$  with  $R_y: x \mapsto (x,y)$ . So  $\mu_y$  is just a copy of  $\alpha$ .

Take measurable  $f: X \times Y \rightarrow [0, \infty]$ . By property (iii) of disintegration:

$$\begin{split} \mu(f) &= \int_{Y} \beta(\mathrm{d}y) \int_{T^{-1}(y)} \mu_{y}(\mathrm{d}(x,y)) f(x,y) \\ &= \int_{Y} \beta(\mathrm{d}y) \int_{T^{-1}(y)} (R_{y})_{*}(\alpha)(\mathrm{d}(x,y)) f(x,y) \quad (\because \mu_{y} = (R_{y})_{*}(\alpha)) \\ &= \int_{Y} \beta(\mathrm{d}y) \int_{X} \alpha(\mathrm{d}x) \underbrace{f \circ R_{y}(x)}_{f(x,y)} \quad \text{(by change of variable)} \end{split}$$

which is precisely Fubini's theorem for s-finite measures.

・同ト・ヨト・ヨト ヨークQへ

**Bayes' Law**: Posterior  $\propto$  Likelihood  $\times$  Prior  $p(\Theta = \theta \mid X = x) = \frac{p(X = x \mid \Theta = \theta) p(\Theta = \theta)}{p(X = x)}$ 

- Bayes' Law says that the posterior times the probability of an observation equals a joint probability.

- But the observation of a continuous quantity usually has probability 0; in which case, Bayes' Law says: "unknown  $\times$  0 = 0"!

(Shan & Ramsey POPL 2017) introduces a new inference algorithm by symbolic manipulation of the prior and an observable expression:

- It can draw exact inference from the observation of a probability-0 continuous quantity.
- Idea: the observable expression denotes a conditional distribution *qua* disintegration of a measure.
- These disintegrations (of s-finite measures) are s-finite kernels, which are denotable by PPL terms.

## **Problem**

Conjecture. Let  $\rho$  be an s-finite measure on  $X \times Y$  and  $\mu$  be s-finite measure on X, satisfying condition (C). Then there exists an s-finite kernel  $k : X \rightsquigarrow Y$  such that  $\rho = \mu \otimes k$ . Further the kernel is unique up to  $\mu$ - $\infty$ -equivalence.

#### Desiderata:

1. Higher order & definability. Take  $\mathcal{L}$  an idealised higher-order PPL; e.g. core Hakaru $\rightarrow$ (?). Extend  $\rho$  and  $\mu$  to  $\mathcal{L}$ -definable measures; prove that k is  $\mathcal{L}$ -definable (Staton ESOP17).

2. Constructiveness / relativised computability. Design an algorithm for constructing k as an  $\mathcal{L}$ -term, given representations of  $\rho$  and  $\mu$  as  $\mathcal{L}$ -terms, via partial evaluation (type-directed / continuation-based); prove correctness via synthetic measure theory.

3. Compositionality / "parametricity law". Replace  $\rho$  and  $\mu$  by s-finite kernels (appropriately typed).

# Outline

- Introduction: s-finite-measure semantics of an idealised 1st-order probabilistic programming language
- 2 Properties of s-finite measures and kernels
- 3 Radon-Nikodým derivatives
- 4 Conditional distribution and disintegration
- 5 Conclusions and further directions

# **Conclusions and further directions**

- S-finite kernels have good closure properties.
- Padon-Nikodým and Disintegration theorems extend to s-finite measures.

#### Further directions

- Methods to construct Radon-Nikodým derivatives and disintegrating measures / kernels
- Deriving disintegration by program transformation & synthesis an approach to Bayesian inference (Shan & Ramsey, POPL 2017)
